Abstract: Sensorless induction motor drives are widely used in industry for their reliability and flexibility. However, rotor flux and speed sensors are required for vector control of induction motor. These sensors are sources of trouble, mainly in hostile environments, and their application reduces the drive robustness. The cost of the sensors is not also negligible. All the reasons lead to development of different sensorless methods for rotor flux and mechanical speed estimation in electrical drives. The paper deals with the speed estimators for applications in sensorless induction motor drive with vector control, which are based on application of model adaptive based Kalman filter methods. The development and DSP implementation of the speed estimators for applications in sensorless drives with induction motor are described in the paper.

Key words: Sensorless control, induction motor drives, Kalman filter estimator, MRAS, modeling, field oriented control, Dspace.

1. Introduction

Induction motor drives have been thoroughly studied in the past few decades and many vector control strategies have been proposed, ranging from low cost to high performance applications. In order to increase the reliability and reduce the cost of the drive, a great effort has been made to eliminate the shaft speed sensor in most high performance induction motor drive applications [1]. Speed estimation is an issue of particular interest with induction motor drives where the mechanical speed of the rotor is generally different from the speed of the revolving magnetic field. The advantages of speed sensorless induction motor drives are reduced hardware complexity and lower cost, reduced size of the drive motor, better immunity, elimination of the sensor cable, increased reliability and less maintenance requirements. The induction motor is however relatively difficult to control compared to other types of electrical motors. For high performance control, field oriented control is the most widely used control strategy. This strategy requires information of the flux in motor, however the voltage and current model observers are normally used to obtain this information. Generally, using the induction motor state equations, the flux and speed can be calculated from the stator voltage and current values. This paper presents model adaptive Kalman estimators for the proposed control.

2. Motor model and vector control strategy

The induction motor mathematical model in d-q coordinates established in a rotor flux oriented reference frame can be written as [2]:

\[ v_{sd} = R_s i_{sd} + \frac{d\psi_{sd}}{dt} - \omega_s \psi_{sq} \]  
\[ v_{sq} = R_s i_{sq} + \frac{d\psi_{sq}}{dt} + \omega_s \psi_{sd} \]  
\[ 0 = R_s i_{sd} + \frac{d\psi_{rd}}{dt} - \omega_d \psi_{rq} \]  
\[ 0 = R_s i_{rq} + \frac{d\psi_{rq}}{dt} + \omega_d \psi_{rd} \]

where the stator and rotor flux linkages are given by:

\[ \psi_{sd} = L_s i_{sd} + L_m i_{rd} \]  
\[ \psi_{sq} = L_s i_{sq} + L_m i_{rq} \]  
\[ \psi_{rd} = L_r i_{rd} + L_m i_{sd} \]  
\[ \psi_{rq} = L_r i_{rq} + L_m i_{sq} \]

The state space representation of the induction motor with the stator currents and the rotor flux linkages components as state variables can be written as:

The basic concept of MRAS is the presence of a reference model which determines the desired states and an adaptive (adjustable) model which generates the estimated values of the states. The error between these states is fed to an adaptation mechanism to generate an estimated value of the rotor speed which is used to adjust the adaptive model. This process continues till the error between two outputs tends to zero [3, 4]. Basic equations of rotor flux based MRAS can be written as:

\[ \Psi_r = \frac{L_m}{L_n} \int (v_r - R_i)dt - L_s \hat{\omega} \]  
\[ \hat{\omega} = \frac{K_p + K_i}{s} e_{\omega} \]  

where \( e_{\omega} = \Psi_{rq} \Psi_{rd} - \Psi_{rd} \Psi_{rq} \)

The reference model (15) is based on stator equations and is therefore independent of the motor speed, while the adaptive model (16) is speed dependant since it is derived from the rotor equation in the stationary reference frame. To obtain a stable nonlinear feedback system, a speed tuning signal \( e_{\omega} \) and a PI controller [5] are used in the adaptation mechanism to generate the estimated speed. The speed tuning signal and the estimated speed expressions can be written as:

\[ e_{\omega} = \Psi_{rq} \Psi_{rd} - \Psi_{rd} \Psi_{rq} \]  
\[ \hat{\omega} = \frac{K_p + K_i}{s} e_{\omega} \]  

where: \( K_p, K_i \) are the proportional and integral constants.

Generally the MRAS observer gives satisfactory speed estimation in the high and medium speed regions. When working at low speed the observer performance deteriorates due to integrator drift and initial condition problems and sensitivity to current measurement noise. Therefore a Kalman filter estimator is proposed to replace the conventional adaptive model (16), (fig. 1) to improve the MRAS scheme performance at load condition, reversal speed and low speed region [6].

![Fig. 1. Kalman filter with MARS observer.](image-url)
4. Presentation of Kalman Filter Algorithm

The Kalman filter algorithm is robust and efficient observer for linear and nonlinear systems, as it is the case of induction motor. The KF use knowledge about the system dynamics and statistical properties of the system, and measurement noise sources to produce an optimal state estimation. The application of the KF algorithm consists on two phases [7]:

**Prediction phase**

\[
\hat{x}_{k+1|k} = A_{k/k} \hat{x}_{k|k} + B_{k/k} u_k
\]

\[
p_{k+1|k} = A_{k/k} \cdot P_{k|k} \cdot A_{k/k}^T + Q_k
\]

\[\hat{x}_k \text{ is the state estimate, } P_k \text{ is the error covariance matrix and } Q_k \text{ covariance matrix of the system noise.} \]

**Correction phase**

At the instant \((k + 1)\), the predicted state variables and their covariance are corrected by using:

\[
K_{k+1} = P_{k+1|k} C_{k}^T (C_{k} P_{k+1|k} C_{k}^T + R_k)^{-1}
\]

\[
p_{k+1|k+1} = (I - K_{k+1} C_{k}) p_{k+1|k}
\]

\[
\hat{x}_{k+1|k+1} = \hat{x}_{k+1|k} + K_{k+1} (y_{k+1} - C_{k} \hat{x}_{k+1|k})
\]

\[K \text{ is the Kalman gain matrix.} \]

5. Design of kalman filter for induction motor

For the implementation of the algorithm of Kalman filter, the model of the induction motor given by (9) must be discrete. The discrete model of the motor is given by the equation below [8]:

\[x_{k+1} = f(A_{k/k} x_{k/k} + B_{k/k} u_k)\]

\[y_k = C_k x_k\]

If the system matrix, the input and output matrices of the discrete system are denoted by \(A_k, B_k \), and \(C_k \), while the state and the output of the discrete system are denoted by \(x_k\) and \(y_k\), then, we define the function:

\[F = f(A_k x_k + B_k u_k)\]

\[H = C_k x_k\]

\[\begin{bmatrix}
1 & -T \left( \frac{R_{e}}{L_{s}} + \frac{1}{\sigma} \right) & T \left( \frac{R_{m}}{L_{s}} \right) & T \left( \frac{R_{n}}{L_{s}} \right) & T \left( \frac{\sigma}{L_{s}} \right) \\
-\sigma T & 1 & -T \left( \frac{R_{e}}{L_{s}} + \frac{1}{\sigma} \right) & T \left( \frac{R_{m}}{L_{s}} \right) & T \left( \frac{R_{n}}{L_{s}} \right) & T \left( \frac{\sigma}{L_{s}} \right) \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0
\end{bmatrix}
\]

\[H = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{bmatrix}
\]

where \(T_c\) is the sampling time

From (26) and (27), the matrices \(F, H, \frac{\partial F}{\partial x}, \frac{\partial H}{\partial x}\) are obtained as follows [9]:

\[\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0
\end{bmatrix}
\]

The implementation of algorithm of the Kalman filter is very easy using the Embedded Matlab function block is based on an M-file written in the MATLAB language because it can be supported by RTI (Real Time Interface). We use only the estimated d-q axis flux with the reference model of MRAS to calculate the rotor speed using a PI controller, the convergence of the algorithm is assured with small time \(T_c=10^{-2}\), use Euler method and the choices of the error covariance matrix \(P\) of the Kalman filter is initially set as a unit matrix and the measurement noise covariance matrix \(R\) and \(Q\) can not be calculated, they must be filled based on experimental investigations. In the following experiments, the best filter performance was obtained with:

\[P = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}, \quad R = \begin{bmatrix}
0.001 & 0 \\
0 & 0.001 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix},
\]

\[Q = \begin{bmatrix}
10^{-2} & 0 & 0 & 0 \\
0 & 10^{-2} & 0 & 0 \\
0 & 0 & 10^{-1} & 0 \\
0 & 0 & 0 & 10^{-2}
\end{bmatrix}
\]

6. Description of Laboratory Setup

The adaptive Kalman filter speed observer has been tested experimentally on a suitable test setup (fig. .2). The test setup consists of the following:

• Three-phase induction motor with rated values shown in Table I;
• Synchronous machine for loading the induction motor;
• Electronic power converter: three-phase diode rectifier and VSI composed of three IGBT modules without any control system;
• Electronic card with voltage sensors (model LEM LV 25-P) and current sensors (model LEM LA 55-P) for monitoring the instantaneous values of the stator phase voltages and currents;
• Voltage sensor (model LEM CV3-1000) for monitoring the instantaneous value of the dc-link.
voltage;
• Incremental encoder (model RS 256-499, 2500 pulses per round), only for comparison measurements;
• dSPACE card (model DS1104) with a PowerPC 604e at 400 MHz and a floating-point digital signal processor (DSP) TMS320F240.

During the real-time operation of the control algorithm, the supervision and capturing of the important data can be done by the CONTROLDESK software provided with the DSP board. Experimental results are captured on the CONTROLDESK and imported to workspace through structure DATA file.

7. Experimental Results and Discussion

The adaptive Kalman filter has been verified experimentally to the test bench described in Section 6. Simulations have been performed in the Matlab-Simulink environment. With regard to the experimental tests the speed observers as well as the whole control algorithm have been implemented by software on the the dSPACE board by employing the Matlab-Simulink Real Time Workshop- Real Time Interface environment. Flux reference is set to its rated value and the dc link voltage is 500 V. Some experimental results were provided to demonstrate the effectiveness of the proposed observer technique. First experiment, the target speed is changed from 0 rpm to 1490 rpm at 1.5 sec with no load applied Fig 3 shows the experimental result of a speed at free acceleration using the estimation of speed, rotor flux and flux angle to control the motor. Additionally, the real speed is measured and compared. It can be seen that there is a very good accordance between real and estimated speed without any steady state error. Fig 4 depicts the trajectories of the electromagnetic torque (a), estimated and measured stator currents evolution (b). It should be noted that the amplitude of the torque ripple is slightly higher. As shown above KF works properly and proves the robustness of the proposed speed observer. We can see the insensibility of the control algorithm at free acceleration test.

Figure 5 shows the speed-sensorless control performance where the load was applied and omitted. The estimated speed coincides exactly with the real speed even the load torque application instant. It is seen that there is only a very small speed estimation error during the speed transient. From these results, it is
shown that the proposed speed-sensorless control algorithm has good performances both during large signal transient operation.

Fig. 5. The reference, actual, estimated and error estimated speed at speed applied a load at 5-7-13-15 sec.

The real and estimated stator currents and the estimated electromagnetic torque, when the motor is running at high speed with load applied, are given by fig. 6a and b. these figures show that the real and the estimated stator currents, the estimates electromagnetic torque are in close agreement.

Fig. 7 shows the behavior the motor at nominal speeds under variable load conditions.

The reference speed is set to 1490 rpm at t=2 sec. Then the set point is changed to -1490 rpm at t=10 sec without any load. It is clear that the speed response exhibits good performances at both dynamics regimes. The result clearly shows that the estimated speed

Fig. 6. a) Response electromagnetic torque, b) estimated stator currents evolution (with load applied).

Fig. 8. a) Response electromagnetic torque, b) estimated stator currents evolution. (reversal speed with no load).
follows the actual speed and the error is not significant.
The results shown in fig. 8a-b illustrate, the electromagnetic torque, actual and estimated stator currents trajectory. These results made the drive remain stable and this condition can be maintained indefinitely.
The second experiment, the controller was tested under with the speed dependent load produced by the synchronous machine.

The reversal speed response of the motor is shown in fig 7 at high speeds without load and in figure 9 under different levels of load torque. From inspection of fig.10a-b, it is possible to verify the excellent behavior of the proposed algorithm. In fact, the error on the estimation both of the stator currents and of the electromagnetic torque are always very small (<2%, by referring to the actual values).

Fig. 9. The reference, actual, estimated and error estimated speed at speed applied a load at 5-7-13-15 sec.

Fig. 10. a) Response electromagnetic torque, b) estimated stator currents evolution. (reversal speed, load applied).

Fig. 11. The reference, actual, estimated and error estimated speed at speed applied at low and reversal speed

Fig. 12. a) Response electromagnetic torque, b) estimated stator currents evolution (at low speed with reversal)
To test the performance of the sensorless drive at low speed without load. The drive is subjected to speed step down from 100 rpm to -100 rpm (see fig 11).

We can see that the speed follow perfectly the speed reference. However, it is important to note that the control system demonstrates a good performance even under those variations. We note that the performance degrades as approaching the low speed region and fails to provide large oscillations.

Figure 12a and b show torque and stator current estimation in the low speed operation.

Excellent tracking performance was obtained no study state error and no overshoot and control performance of the drive is acceptable for load disturbance. The gotten results show the effectiveness of the proposed control scheme.

8. Conclusion

Both observers presented in the paper can estimate the speed in an electrical drive system. The values of the speed estimated on-line can be used by the control of the electrical drive systems in speed range. The main features are the following:
- The rotor speed of the motor is estimated by reference model with Kalman filter observers.
- To obtain a high-dynamic current sensorless control, a current to voltage feed forward decoupling and a good dynamic correction are obtained.
- Moreover, an accurate dynamic limitation of the real electromagnetic torque is obtained.
- The final algorithm can be implemented with relatively few instructions with execution times of each algorithm 167 μS.
- Results of the dynamic and steady state behavior of a sensorless speed control of an induction motor are given.
- The results were satisfactory.
- Both at low, at load applied, at high and reversal motor speed the proposed control scheme is working very well and proves a robustness of the proposed control structure in dSPACE environment.
- The described control system is a solution without mechanical sensors for a wide range of applications where good steady state and dynamic properties are required.

At present, sensor-based controls are still widely used in industrial and transportation applications. But in the near future, speed sensorless-based drive systems will become a practical reality and will be used in many industrial applications. Sensorless-based systems will provide higher reliability and operation in adverse environmental conditions at a lower cost.
